

Healthcare Disease & Risk Analysis

Key Project Insights • Power BI Portfolio Project

Executive Summary

The dashboard analyzes 1,000 patient records across disease patterns, demographics, clinical indicators, lifestyle factors, and analytical health-risk categories.

1. Disease Burden

646 of 1,000 patients (64.6%) are diagnosed with a disease. Diabetes is the most frequently represented diagnosis, followed by Hypertension. High Cholesterol, Heart Disease, and Obesity are also represented.

2. Blood Pressure Risk

High blood pressure is the largest blood-pressure risk category, with approximately 539 patients. The Normal category contains about 270 patients, followed by Elevated and Very High categories.

3. BMI Pattern

Overweight is the largest BMI category. The concentration of patients in overweight and obese categories makes BMI an important factor in the overall risk analysis.

4. Lifestyle Risk Distribution

Lifestyle Risk	Patients	Share
Low	456	45.6%
Moderate	438	43.8%
High	106	10.6%

Nearly 9 out of 10 patients fall into Low or Moderate lifestyle risk, while 10.6% are classified as High lifestyle risk.

5. High-Risk Patients

101 patients are classified as High Risk, representing approximately **10.1%** of the total population under the project's analytical risk model.

6. Cholesterol Risk

The **Desirable** cholesterol category is the largest group. A substantial number fall into **Borderline High**, while a smaller group falls into High.

7. Disease Patterns by Age

Disease composition varies across age groups. Older age groups show a stronger presence of several chronic-disease categories, making age segmentation useful for risk analysis.

8. Disease Patterns by Gender

Both male and female patients contain multiple disease categories, but the disease mix is not identical, making gender useful for comparison.

Top 5 Interview-Ready Insights

- 64.6% of patients are diagnosed with a disease, with Diabetes and Hypertension among the most represented diagnoses.

- High blood pressure is the largest BP risk category, with approximately 539 patients.
- Overweight and Obese categories represent a substantial portion of the patient population.
- 101 patients (10.1%) are classified as High Risk under the project's analytical risk model.
- Lifestyle risk is concentrated in Low and Moderate categories, while 10.6% are High risk.

Important: These insights are based on the project dataset and analytical scoring rules. The risk categories are created for Power BI portfolio analysis and are not clinical diagnostic criteria.
